# Week 3

# Algorithms + Data Structures = Programs

- Title of Niklaus Wirth's introduction to Pascal
- Traditionally, algorithms come first
- Structured programming
  - Design a set of procedures for specific tasks
  - Combine them to build complex systems
- Data representation comes later
  - Design data structures to suit procedural manipulations

# Object oriented design

# Object Oriented design

- Reverse the focus
- First identify the data we want to maintain and manipulate
- Then identify algorithms to operate on the data
- Claim: works better for large systems
- Example: simple web browser
  - 2000 procedures manipulating global data
  - ...vs 100 classes, each with about 20 methods
  - Much easier to grasp the design
  - Debugging: an object is in an incorrect state
  - Search among 20 methods rather than 2000 procedures

# Object Oriented design: Example

- An order processing system typically involves
  - Items
  - Orders
  - Shipping addresses
  - Payments
  - Accounts
- What happens to these objects?
  - Items are added to orders
  - Orders are shipped, cancelled
  - Payments are accepted, rejected

# Designing objects

- Behaviour — what methods do we need to operate on objects?
- State — how does the object react when methods are invoked?
  - State is the information in the instance variables
  - Encapsulation — should not change unless a method operates on it
- Identity — distinguish between different objects of the same class
  - State may be the same — two orders may contain the same item
- These features interact
  - State will typically affect behaviour
  - Cannot add an item to an order that has been shipped
  - Cannot ship an empty order

# Relationship between classes

- Dependence
  - `Order` needs `Account` to check credit status
  - `Item` does not depend on `Account`
  - Robust design minimizes dependencies, or coupling between classes
- Aggregation
  - `Order` contains `Item` objects
- Inheritance
  - One object is a specialized versions of another
  - `ExpressOrder` inherits from `Order`
  - Extra methods to compute shipping charges, priority handling

# Inheritance

# A Java class

- An `Employee` class
- Two private instance variables
- Some constructors to set up the object
- Accessor and mutator methods to set instance variables
- A public method to compute bonus

```
public class Employee{
  private String name;
  private double salary;

  // Some Constructors ...

  // "mutator" methods
  public boolean setName(String s){ ... }
  public boolean setSalary(double x){ ... }

  // "accessor" methods
  public String getName(){ ... }
  public double getSalary(){ ... }

  // other methods
  public double bonus(float percent){
     return (percent/100.0)*salary;
  }
}
```

# Subclasses

- Managers are special types of employees with extra features

```
public class Manager extends Employee{
     private String secretary;
     public boolean setSecretary(name s){ ... }
     public String getSecretary(){ ... }
}
```

- `Manager` objects inherit other fields and methods from `Employee`
  - Every `Manager` has a `name`, `salary` and methods to access and manipulate these.
- `Manager` is a subclass of `Employee`
  - Think of subset

# Subclasses

- `Manager` objects do not automatically have access to private data of parent class.
  - Common to extend a parent class written by someone else
- How can a constructor for `Manager` set instance variables that are private to `Employee`?
- Some constructors for `Employee`
- Use parent class's constructor using `super`
- A constructor for `Manager`

```
public class Employee{
  ...
  public Employee(String n, double s){
     name = n; salary = s;
  }
  public Employee(String n){
     this(n,500.00);
  }
}
```

```
public class Manager extends Employee{
  ..
  public Manager(String n, double s, String sn){
     super(n,s);   /* super calls
                      Employee constructor */
     secretary = sn;
  }
}
```

# Inheritance

- In general, subclass has more features than parent class
  - Subclass inherits instance variables, methods from parent class
- Every `Manager` is an `Employee`, but not vice versa!
- Can use a subclass in place of a superclass

```
Employee e = new Manager(...)
```

- But the following will not work

```
Manager m = new Employee(...)
```

- Recall
  - `int[] a = new int[100];`
  - Why the seemingly redundant reference to `int` in `new`?
- One can now presumably write

```
Employee[] e = new Manager(...)[100]
```

# Subclasses and inheritance

- A subclass extends a parent class
- Subclass inherits instance variables and methods from the parent class
- Subclasses cannot see private components of parent class
- Subclass can add more instance variables and methods
- Can also override methods

```
public class Employee{
  private String name;
  private double salary;

  public boolean setName(String s){ ... }
  public boolean setSalary(double x){ ... }
  public String getName(){ ... }
  public double getSalary(){ ... }

  public double bonus(float percent){
     return (percent/100.0)*salary;
  }
}

public class Manager extends Employee{
  private String secretary;
  public boolean setSecretary(name s){ ... }
  public String getSecretary(){ ... }
}
```

# Polymorphism:
# Dynamic Dispatch(late binding)

# Dynamic dispatch

- `Manager` can redefine `bonus()`

```
double bonus(float percent){
   return 1.5*super.bonus(percent);
}
```

  - Uses parent class `bonus()` via `super`
  - Overrides definition in parent class
- Consider the following assignment

```
Employee e = new Manager(...)
```

- Can we invoke `e.setSecretary()`?
  - `e` is declared to be an `Employee`
  - Static typechecking — `e` can only refer to methods in `Employee`
- What about `e.bonus(p)`? Which `bonus()` do we use?
  - Static: Use `Employee.bonus()`
  - Dynamic: Use `Manager.bonus()`
- Dynamic dispatch (dynamic binding, late method binding, ...) turns out to be more useful
  - Default in Java, optional in languages like C++ (`virtual` function)

# Polymorphism

- Every `Employee` in `emparray` "knows" how to calculate its `bonus` correctly!
- Recall the event simulation loop that motivated Simula to introduce objects
- Also referred to as runtime polymorphism or inheritance polymorphism

```
Employee[] emparray = new Employee[2];
Employee e = new Employee(...);
Manager e = new Manager(...);

emparray[0] = e;
emparray[1] = m;

for (i = 0; i < emparray.length; i++){
  System.out.println(emparray[i].bonus(5.0);
}
```

# Type casting

- Consider the following assignment

  `Employee e = new Manager(...)`

- Can we get `e.setSecretary()` to work?
  - Static type-checking disallows this
- Type casting — convert `e` to `Manager`

  `((Manager) e).setSecretary(s)`
- Cast fails (error at run time) if `e` is not a `Manager`
- Can test if `e` is a `Manager`

```
if (e instanceof Manager){
  ((Manager) e).setSecretary(s);
}
```

- A simple example of reflection in Java
  - "Think about oneself"
- Can also use type casting for basic types

```
double d = 29.98;
int nd = (int) d;
```

# Method Overloading

# Functions, signatures and overloading

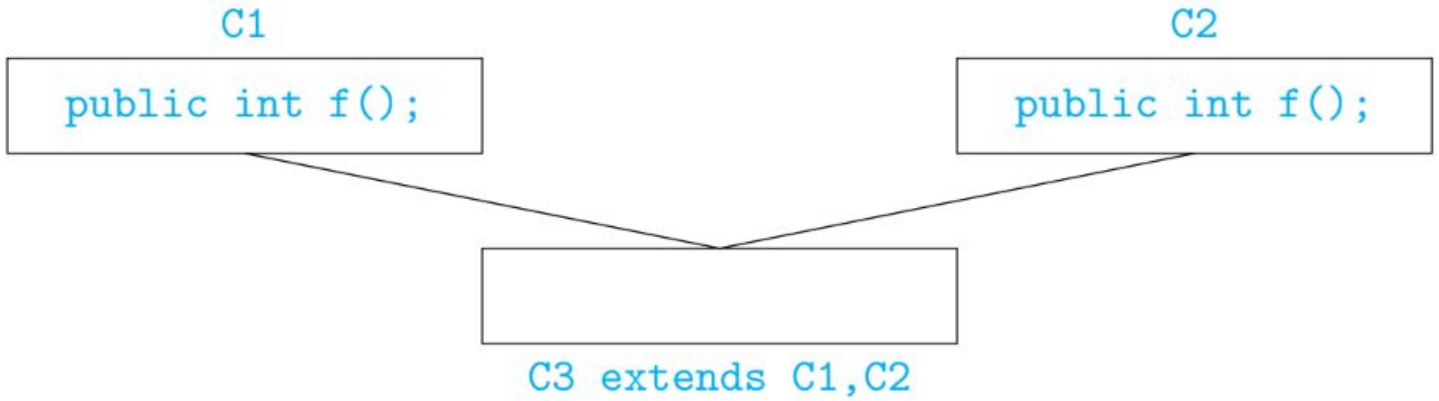
- Signature of a function is its name and the list of argument types
- Can have different functions with the same name and different signatures
  - For example, multiple constructors
- Java class `Arrays` has a method `sort` to sort arbitrary scalar arrays
- Made possible by overloaded methods defined in class `Arrays`

```
double[] darr = new double[100];
int[] iarr = new int[500];
...
Arrays.sort(darr);
  // sorts contents of darr
Arrays.sort(iarr);
  // sorts contents of iarr

class Arrays{
  ...
  public static void sort(double[] a){..}
     // sorts arrays of double[]
  public static void sort(int[] a){..}
     // sorts arrays of int[]
  ...
}
```

# Multiple Inheritance

# Multiple inheritance



- Can a subclass extend multiple parent classes?
- If `f()` is not overridden, which `f()` do we use in `C3`?
- Java does not allow multiple inheritance
- C++ allows this if `C1` and `C2` have no conflict

# Java Class hierarchy

# Java class hierarchy

- No multiple inheritance — tree-like
- In fact, there is a universal superclass `Object`
- Useful methods defined in `Object`

```
public boolean equals(Object o)  // defaults to pointer equality

public String toString()         // converts the values of the
                                 // instance variables to String
```

- For Java objects `x` and `y`, `x == y` invokes `x.equals(y)`
- To print `o`, use `System.out.println(o+"");`
  - Implicitly invokes `o.toString()`

# Java class hierarchy

- Can exploit the tree structure to write generic functions
  - Example: search for an element in an array

```
public int find (Object[] objarr, Object o){
  int i;
  for (i = 0; i < objarr.length(); i++){
      if (objarr[i] == o) {return i};
  }
  return (-1);
}
```

- Recall that `==` is pointer equality, by default
- If a class overrides `equals()`, dynamic dispatch will use the redefined function instead of `Object.equals()` for `objarr[i] == o`

# Overriding functions

# Overriding functions

- For instance, a class `Date` with instance variables `day`, `month` and `year`
- May wish to override `equals()` to compare the object state, as follows

```
public boolean equals(Date d){
  return ((this.day == d.day) &&
          (this.month == d.month) &&
          (this.year == d.year));
}
```

- Unfortunately, `boolean equals(Date d)` does not override `boolean equals(Object o)`!

# Overriding functions

- For instance, a class `Date` with instance variables `day`, `month` and `year`
- May wish to override `equals()` to compare the object state, as follows

```
public boolean equals(Date d){
  return ((this.day == d.day) &&
          (this.month == d.month) &&
          (this.year == d.year));
}
```

- Unfortunately, `boolean equals(Date d)` does not override `boolean equals(Object o)`!
- Should write, instead

```
public boolean equals(Object d){
  if (d instanceof Date){
    Date myd = (Date) d;
    return ((this.day == myd.day) &&
            (this.month == myd.month) &&
            (this.year == myd.year));
  }
  return(false);
}
```

  - Note the run-time type check and the cast

# Overriding functions

- Overriding looks for "closest" match
- Suppose we have `public boolean equals(Employee e)` but no `equals()` in `Manager`
- Consider

```
Manager m1 = new Manager(...);
Manager m2 = new Manager(...);
...
if (m1.equals(m2)){ ... }
```

- `public boolean equals(Manager m)` is compatible with both `boolean equals(Employee e)` and `boolean equals(Object o)`
- Use `boolean equals(Employee e)`

# Subclasses, subtyping and inheritance

- Class hierarchy provides both subtyping and inheritance
- Subtyping
  - Capabilities of the subtype are a superset of the main type
  - If `B` is a subtype of `A`, wherever we require an object of type `A`, we can use an object of type `B`
  - `Employee e = new Manager(...);` is legal
- Inheritance
  - Subtype can reuse code of the main type
  - `B` inherits from `A` if some functions for `B` are written in terms of functions of `A`
  - `Manager.bonus()` uses `Employee.bonus()`

# Subtyping vs inheritance

- Recall the following example
  - `queue`, with methods `insert-rear`, `delete-front`
  - `stack`, with methods `insert-front`, `delete-front`
  - `deque`, with methods `insert-front`, `delete-front`, `insert-rear`, `delete-rear`
- What are the subtype and inheritance relationships between these classes?
- Subtyping
  - `deque` has more functionality than `queue` or `stack`
  - `deque` is a subtype of both these types
- Inheritance
  - Can suppress two functions in a `deque` and use it as a `queue` or `stack`
  - Both `queue` and `stack` inherit from `deque`

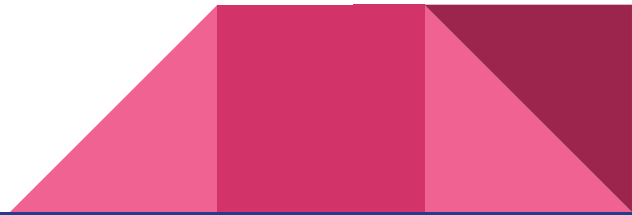
# Subclasses, subtyping and inheritance

- Class hierarchy represents both subtyping and inheritance
- Subtyping
  - Compatibility of interfaces.
  - `B` is a subtype of `A` if every function that can be invoked on an object of type `A` can also be invoked on an object of type `B`.
- Inheritance
  - Reuse of implementations.
  - `B` inherits from `A` if some functions for `B` are written in terms of functions of `A`.
- Using one idea (hierarchy of classes) to implement both concepts blurs the distinction between the two

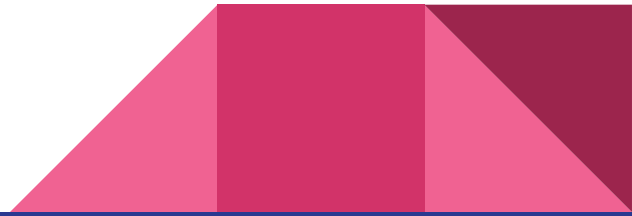
# Access Modifiers

# Access modifiers

- Access modifiers are keywords that can be used to control the visibility of instance variables, methods, and class.
- The four access modifiers in Java are public, protected, default, and private.
- Private
- When instance variables and methods are private ,they can be accessed only inside the class in which they are defined.
- They cannot be accessed from outside the class even in subclass.



- Public
- When instance variables and method is public, they can be accessed within the same class as well as from outside the different classes.
- It also includes access within the same package and also from outside the package.
-



# static components

- Use `static` for components that exist without creating objects
  - Library functions, `main()`, ...
  - Useful constants like `Math.PI`, `Integer.MAX_VALUE`
- These `static` components are also `public`
- Do `private static` components make sense?
- Internal constants for bookkeeping
  - Constructor sets unique id for each order

```
public class Order {
  private static int lastorderid = 0;

  private int orderid;
  ....

  public Order(...) {
    lastorderid++;
    orderid = lastorderid;
    ...
  }
```

- `lastorderid` is private static field
- Common to all objects in the class
- Be careful about concurrent updates!

# `final` components

- `final` denotes that a value cannot be updated
- Usually used for constants (`public` and `static` instance variables)
  - `Math.PI`, `Integer.MAX_VALUE`
- What would `final` mean for a method?
  - Cannot redefine functions at run-time, unlike Python!
- Recall overriding
  - Subclass redefines a method available with the same signature in the parent class
- A `final` method cannot be overridden

# Encapsulation

# public vs private

- Faithful implementation of encapsulation necessitates modifiers `public` and `private`
  - Typically, instance variables are `private`
  - Methods to query (accessor) and update (mutator) the state are `public`
- Can `private` methods make sense?
- Example: a `Stack` class
  - Data stored in a private array
  - Public methods to push, pop, query if empty

```
public class Stack {
  private int[] values; // array of values
  private int tos;      // top of stack
  private int size;     // values.length

  /* Constructors to set up values array */

  public void push (int i){
    ....
  }

  public int pop (){
    ...
  }

  public boolean is_empty (){
    return (tos == 0);
  }
}
```

# private methods

- Example: a `Stack` class
  - Data stored in a private array
  - Public methods to push, pop, query if empty
- `push()` needs to check if stack has space
- Deal gracefully with stack overflow
  - `private` methods invoked from within `push()` to check if stack is full and expand storage

```
public class Stack {
  ...
  public void push (int i){
    if (stack_full()){
      extend_stack();
    }
    ... // Usual push operations
  }
  ...
  private boolean stack_full(){
    return(tos == size);
  }

  private void extend_stack(){
    /* Allocate additional space,
       reset size etc */
  }
}
```

# Accessor and mutator methods

- Public methods to query and update private instance variables
- `Date` class
  - Private instance variables `day`, `month`, `year`
  - One public accessor/mutator method per instance variable
- Inconsistent updates are now possible
  - Separately set invalid combinations of `day` and `month`
- Instead, allow only combined update

```
public class Date {
  private int day, month year;

  public void getDay(int d) {...}
  public void getMonth(int m) {...}
  public void getYear(int y) {...}

  public void setDate(int d, int m, int y) {
    ...
    // Validate d-m-y combination
  }

}
```
